ON THE NONLINEARITY OF POWER FUNCTIONS

PHILIPPE LANGEVIN, GRIM UNIVERSITÉ DE TOULON.

Let L be an extension of degree m of the field $\mathbf{F}_2$. Let μ be the canonical additive character of L. The *Fourier coefficient* of the polynomial $f(X) \in L[X]$ at the point $a \in L$ is defined by $\widehat{f}(a) = \sum_{x \in L} \mu(f(x) + a.x)$. The *spectral magnitude* of f, $R(f) := \sup_{a \in \mathbf{F}_2} |\widehat{f}(a)|$, is one of the most important cryptographic parameters associated to f [10]. The determination of the spectral magnitude of power functions $x \mapsto x^s$ is an old open problem from different frameworks [5, 9] : two zeros cyclic codes (Kasami, Charpin), correlation of sequences (Gold, Niho, Welch) and boolean functions (Canteaut, Dobbertin). The main questions are : what is the spectral magnitude, say $L(s, m)$ of the power function $x \mapsto x^s$, what is the minimal value $L(m)$ of the $L(s, m)$ and what are the *good* exponents s such that $L(s, m) = L(m)$? Most of the papers on the subject use McEliece's theorem on the divisibility of weight of cyclic codes whose the proof [2, 3, 6] is very similar to those of the Ax 's theorem on the divisibility of the number of zeros of algebraic equations [8]. Here we apply Stickelberger's congruences on Gauss sums [7] to explore the non-linearity of power functions.

Conjecture 1 (Welch). *If m is even then $L(m) = 2^{(m+2)/2}$.*

Let m be an odd integer. By Sidelnikov, we know that $L(m) = 2^{(m+1)/2}$. The set of good exponents is closed under the action of the group generated by the transformations $s \mapsto s^{-1}$ and $s \mapsto 2s$ modulo $q - 1$. We say that two exponents are equivalent if they are in the same orbit. Up to equivalence, all the known good exponents are summarized in the table (1). They share out in four class and usually one conjectures that all the good exponents are known. The Stickelberger's congruences on Gauss sums suggests the introduction of the mapping

$$V : j \mapsto S(-j) + S(j/s)$$

type	s	condition	proof	date
Gold	$2^k + 1$	$(k, m) = 1$	folklore	1968
Kasami	$2^{2k} - 2^k + 1$	$(k, m) = 1$	Kasami.	1971
Welch	$2^t + 3$		DCC(†)	1999
Niho	$2^t + 2^{(m-1)/4} - 1$	$m \equiv 1\,(4)$	DHX(‡)	2000
Niho	$2^t + 2^{(3m-1)/4} - 1$	$m \equiv 3\,(4)$		

TABLE 1. Good exponents, (†)Canteaut, Charpin, Dobbertin, (‡) Dobbertin, Hollmann, Xiang.

where $S(k)$ denotes the sum of the bits of $k \mod q-1$ when j ranges $[0, q-2]$. In particular, we introduce the following notations

$$W_s = \min_{1 \le j \le q-2} V(j), \quad J_s = \{j \mid V(j) = W_s\}, \quad P_s(X) = \sum_{j \in J} X^j.$$

Proposition 1. *The Fourier coefficients of x^s have a dyadic valuation greater or equal to W_s. Moreover, the multiplicative isomorphism $a \mapsto \bar{a} = \chi(a^s)$* mod 2 *shows that $\widehat{f}(a) \equiv 0 \mod 2^{W+1} \Leftrightarrow P(\bar{a}) = 0$.*

Theorem 1. *If $W_s = \frac{m+1}{2}$ and $P_s(X)$ has 2^{m-1} roots in L then s is a good exponent.*

Corollary 1. *If $W_s = \frac{m+1}{2}$ and $\sum_{j \in J} X^j$ is a permutation polynomial then s is a good exponent.*

The corollary gives a strategy to eventually find new good exponents. Indeed it suffice for example to look for among the s such that J_s reduces to a single cyclotomic class. On the basis of numerical experiments :

Conjecture 2. *An integer s has Gold type if and only if $W_s = t+1$ and $J_s = \{1, 2, \ldots, 2^{m-1}\}$.*
